Integumentary system (chapter 5)

Page 1

Membranes

Sheet-like organs that form protective coverings and barriers in the body

• Most membranes contain a layer of epithelial tissue over a layer of dense connective tissue

• The four major types of membranes are cutaneous, mucus, serous, and synovial

Fig 4.4

Integumentary system

The skin and the organs within the skin (sweat and oil glands, hair, nails)

• Function = To protect the body

Cutaneous membrane (The skin)

A membrane that lines the outside of the body to (a) protect the body from infection and other environmental hazards, and (b) to retain the body's fluids

• The skin is composed of two layers

 $\sqrt{\text{Epidermis}}$ = stratified squamous epithelial tissue on outside

 $\sqrt{\text{Dermis}}$ = dense connective tissue underneath epidermis

• The hypodermis (subcutaneous) = An adipose layer under the skin (it is not considered part of the skin)

Fig 5.2

Integumentary system

Epidermis

Stratified squamous epithelial cells on the outside of the skin

• The lower-most cell layer of the epidermis = Stratum basale $\sqrt{\text{Cells constantly dividing}}$; New cells get pushed upward

- As the cells move upward, they slowly die and fill with keratin protein (a hard, waterproof protein)

 $\sqrt{\text{Melanocytes}}$ = Cells in stratum basale that make melanin (anti-UV pigment)

• The upper-most cell layer of the epidermis = Stratum corneum

 $\sqrt{\text{Dead cells completely filled with keratin}}$

 $\sqrt{}$ The thickest of the epithelial strata

Figs 5.2, 5.4, and 5.5

Dermis

Dense connective tissue below the epidermis

• The upper part of the dermis has papillae (wavy upward projections that indent the epidermis)

The dermis is rich in blood vessels and nerve endings

 √ The blood vessels (a) supply the stratum basale cells with the
 nutrients and oxygen they need for growth, and (b) regulate
 body temperature

 $\sqrt{}$ The nerves sense touch, temperature, and damage

• Sweat glands and sebaceous (oil) glands are located in the dermis

 $\sqrt{\text{Gland}}$ = any tissue that secretes (makes and releases) substances

Figs 5.2 and 5.7

Integumentary system

Skin color is due to a combination of pigments and blood in the skin:

• Changes in the blood in skin can cause skin color changes

 $\sqrt{\text{Erythema}} = \text{Redness due to excess blood in skin's blood}$ vessels

 $\sqrt{\text{Cyanosis}} = \text{Blue skin due to low oxygen blood}$

 $\sqrt{\text{Jaundice}} = \text{Yellow skin due to bile from faulty liver}$

Fig 5.8

Skin appendages

The organs in the integumentary system that assist the skin in protecting the body

- The sweat glands, sebaceous (oil) glands, hair, and nails
- All skin appendages are located in the dermis

Sebaceous glands (oil glands)

Glands that release oily sebum

- Sebum softens the hair and the skin and kills bacteria
- Usually found as part of a hair follicle

Page 3

Integumentary system

Page 4

Sweat glands

Glands that release sweat (water with salts, and other solutes) to cool the body

Fig 5.14

Hair

Long thin skin appendages made of dead keratin-filled epithelial cells

- Shaft = the part of a hair above the skin
- Root = the part of a hair below the skin

 $\sqrt{\text{Follicle}}$ = The cells that surround the hair root

 $\sqrt{\text{Each follicle is connected to a sebaceous gland and an arrector pili (a smooth muscle organ that raises the hair when we are frightened or cold)}$

Fig 5.11

Nails

Structures at the ends of fingers and toes made of dead keratin-filled epithelial cells

Fig 5.13
